EUROPEAN ALGAE  
BIOMASS ASSOCIATION

# European Algae Biomass Association

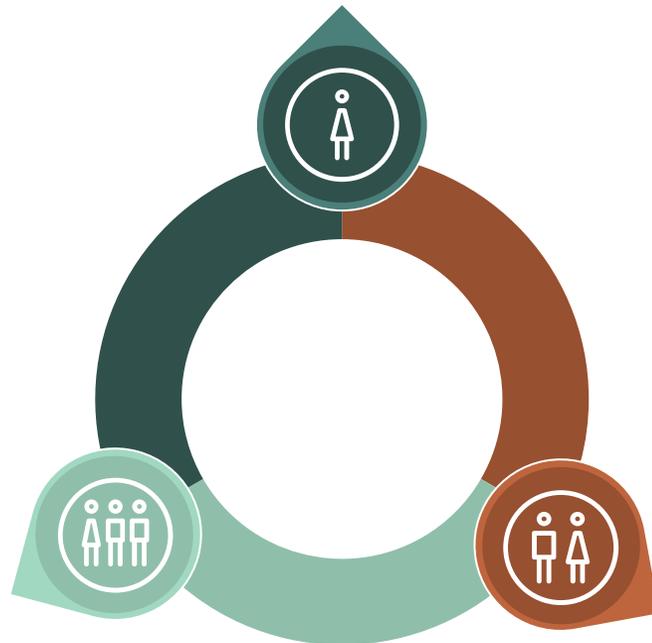

## Objective

Promote mutual interchange and cooperation in the field of algae biomass production and use, including biofuels uses and all other utilizations

Established in  
Florence in June 2009

## Target

Its main target is to act as a catalyst for fostering synergies among scientists, industrialists and decision makers in order to promote the development of research, technology and industry

## Why?

This webinar aims to follow-up the 2019 Workshops and Technical webinars in 2020. The webinar will provide a **global overview** and **details** about the **algae biomass sector** either about **specific algae** as *Haematococcus*, *Nannochloropsis*, *Arthrospira* (spirulina), and **products from algae** as phycocyanin, fucoxanthin and biostimulants or algae antivirals. The Maxi Webinar will bring a global vision about the algae biomass sector.

The European Algae Biomass Association (EABA) aims to promote a strong link between **science, technology and business** in the algae biomass sector. Both microalgae and seaweed will be presented. It is very relevant to bring together the main stakeholders for knowledge exchange and collaboration and to learn from others. We provide specific content with a unique opportunity for training and learning in a networking environment.

# Nutrient recovery from wastewater streams by microalgae: Status and prospects

Ting Cai<sup>1</sup>, Stephen Y. Park<sup>1</sup>, Yebo Li<sup>1</sup>✉

**There is a wide range of evidences about the use of microalgae for inorganic nutrient recovery from wastewater with different cultivation systems.**

## Abstract

Disposal of wastewater often results in high nutrient loading into aquatic environments, which may lead to favorable conditions for undesirable phytoplankton blooms. Microalgae are efficient in removing nitrogen, phosphorus, and toxic metals from wastewater under controlled environments. If key nutrients in the wastewater stream can be used to grow microalgae for biofuel production, the nutrients can be removed, thus significantly reducing the risk of harmful phytoplankton overgrowth. This review paper summarizes the major nutrient components of different wastewater streams, the mechanisms of algal nutrient uptake, nutrient removal performance of various species of microalgae when cultured in wastewater, and current microalgae production systems. Finally, new algae cultivation technologies applicable for biofuel production and nutrient recovery in polluted water bodies are discussed.

  - 4.3. Innovative submersible aquatic algae cultivation technology . . . . .

## 5. Conclusions

Although the ability of microalgae to assimilate excess nutrients from the environment has been thoroughly studied, due to the complex characteristics of wastewater, the tests of growing algae in wastewater are mostly at laboratory scale. Pilot-scale algae cultivation continues to face many issues including contamination, inconsistent wastewater components, and unstable biomass production. The major challenge associated with cultivating algae in nutrient-rich, natural water bodies comes from the design of the cultivation system. Further research is needed to identify algae species and optimize operating parameters for lipid production that can be used to prevent eutrophication of water bodies.

**KEYWORDS**  
Microalgae;  
Wastewater treatment

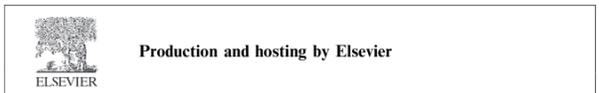

**Abstract** Organic and inorganic substances which were released into the environment as a result of domestic, agricultural and industrial water activities lead to organic and inorganic pollution. The normal primary and secondary treatment processes of these wastewaters have been introduced in a growing number of places, in order to eliminate the easily settled materials and to oxidize the organic material present in wastewater. The final result is a clear, apparently clean effluent which is discharged into natural water bodies. This secondary effluent is, however, loaded with inorganic nitrogen and phosphorus and causes eutrophication and more long-term problems because of refractory organics and heavy metals that are discharged. Microalgae culture offers an interesting step for wastewater treatments, because they provide a tertiary biotreatment coupled with the production of potentially valuable biomass, which can be used for several purposes. Microalgae cultures offer an elegant solution to tertiary and quinary treatments due to the ability of microalgae to use inorganic nitrogen and phosphorus for their growth. And also, for their capacity to remove heavy metals, as well as some toxic organic compounds, therefore, it does not lead to secondary pollution. In the current review we will highlight on the role of micro-algae in the treatment of wastewater.

## 14. Conclusion

\* Algae can be used in wastewater treatment for a range of purposes, including:  
1. reduction of BOD,  
2. removal of N and/or P,  
3. inhibition of coliforms,  
4. removal of heavy metals

\* The high concentration of N and P in most wastewaters also means these wastewaters may possibly be used as cheap nutrient sources for algal biomass production. This algal biomass could be used for:  
1. methane production,  
2. composting,  
3. production of liquid fuels ((pseudo-vegetable fuels),  
4. as animal feed or in aquaculture and  
5. production of fine chemicals.

Received: 1 April 2019; Accepted: 24 May 2019; Published: 30 May 2019

**Abstract:** Concerns about environmental safety have led to strict regulations on the discharge of final brewery effluents into water bodies. Brewery wastewater contains huge amounts of organic compounds that can cause environmental pollution. The microalgae wastewater treatment method is an emerging environmentally friendly biotechnological process. Microalgae grow well in nutrient-rich wastewater by absorbing organic nutrients and converting them into useful biomass. The harvested biomass can be used as animal feed, biofertilizer, and an alternative energy source for biodiesel production. This review discusses conventional and current brewery wastewater treatment methods, and the application and potential of microalgae in brewery wastewater treatment. The study also discusses the benefits as well as challenges associated with microalgae brewery and other industrial wastewater treatments.

**Keywords:** brewery industry; wastewater; microalgae; environmental protection

## 7. Conclusions

As the brewery industry continues to expand, the amount of wastewater it produces will continue to increase and thus its negative impact on the environment. In order to safeguard the environment, biological methods such as aerobic and anaerobic treatments are mostly used due to their capability to remove high organic loads and COD. However, these methods are associated with high capital and operating costs. Moreover, these methods are only applied as pre-treatment options and the water may require further treatment.

In this review, MBR, activated carbon and MFC methods have shown some promising results that have great potential for brewery wastewater treatment. However, high energy consumption and maintenance cost may be an inhibitory factor. Membrane filtration is being used for industrial brewery effluent and other industrial wastewater treatment. The technology is also being applied in drinking water and wastewater reuse. This technology has undergone speedy improvement in terms of quality and costs in recent times and could be used as a polishing step after microalgae treatment. Activated carbon-based treatment methods are less expensive, efficient in organic pollutant removal and can be a suitable treatment option for the brewery industry but, it may be faced with environmental and health concerns due to the use of carbon/coal for the treatment of effluent on a large scale.

This study has shown some promising outcome from microalgae treatment methods. Microalgae treatment has high potential in brewery wastewater treatment. The technology is reliable, eco-friendly, and cost effective. Moreover, it is effective in removing ammonia and phosphorus from brewery effluents. Microalgae wastewater treatment has numerous benefits that have been outlined in this article. However, this technology requires the integration of other treatment methods in order to improve upon the final effluent for the protection of the environment. Currently, there are not many works about these integration options. This requires urgent investigation of other treatment methods with microalgae-based treatment methods, especially regarding color and odor removal from brewery effluent for its possible reuse. Further scientific research should be focused on finding more microalgae strains that are robust enough to adapt to stress and other growth inhibitors to effectively treat brewery and other industrial wastewaters for total protection of the environment.

**Microalgae brewery wastewater treatment is effective in removing ammonia and phosphorus but requires the integration of other treatment methods in order to improve the final effluent.**

# Wastewater treatment

## New technologies are necessary

New technologies are requested to allow:

- To reduce the energy consumption of conventional systems
- To recover the nutrients contained into wastewater
- To minimize the emissions of CO<sub>2</sub> and other GHG
- To accomplish the more restrictive regulations in N-P release
- To be installed in small cities at low cost thus allowing to treat 100% of WW
- Robust and don't requiring expert supervision
